Problem: Adoption of RL in Healthcare

RL has recently found many applications in the **healthcare** domain.

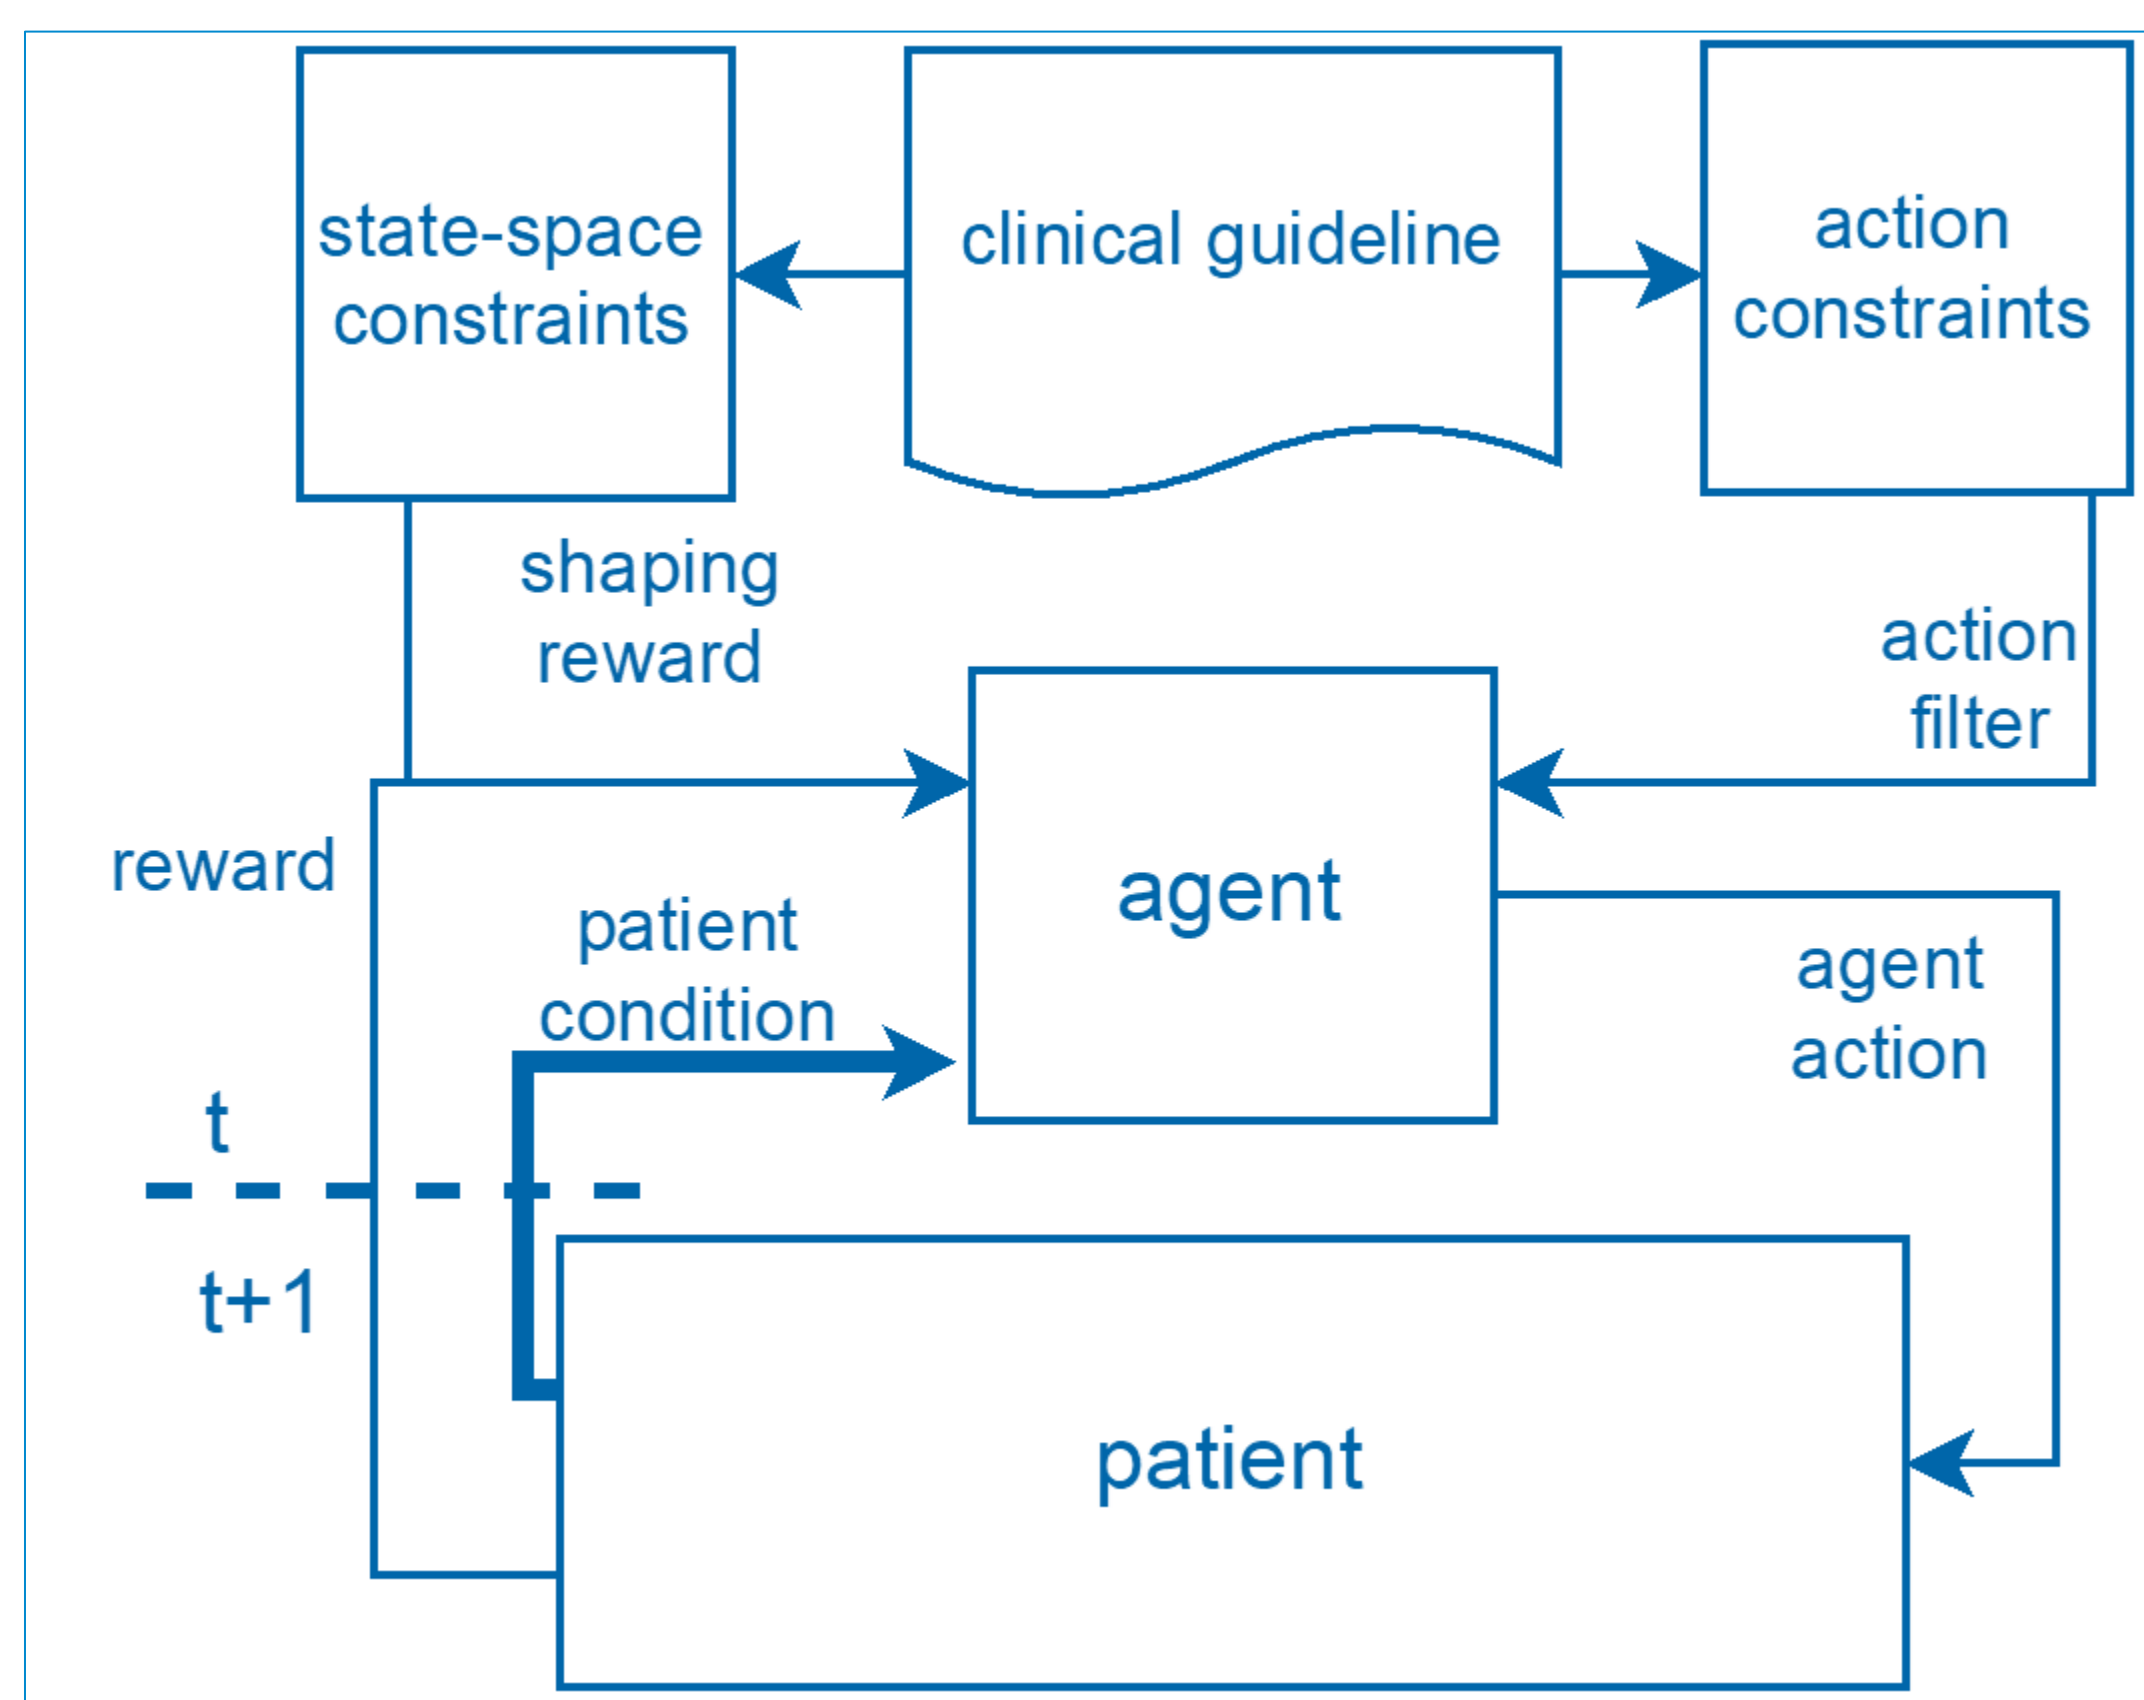

A **key challenge** in adopting RL-based solution in clinical practice, however, is the **inclusion of existing knowledge**.

Existing knowledge from medical guidelines may **improve safety** of solutions, produce a **better balance** between **short- and long-term** outcomes for patients, and **increase trust and adoption** by clinicians.

Methodology

A framework for including knowledge in **medical guidelines** in RL

Components for enforcing **safety constraints** and **reward shaping** to balance short- and long-term outcomes

1) **Clinical guidelines** are manually encoded into **state-space constraints** and **action constraints** in collaboration with clinicians.

2) **Action constraints** describe allowable treatment decisions. These are enforced with a **filter** that removes all non-compliant treatment actions

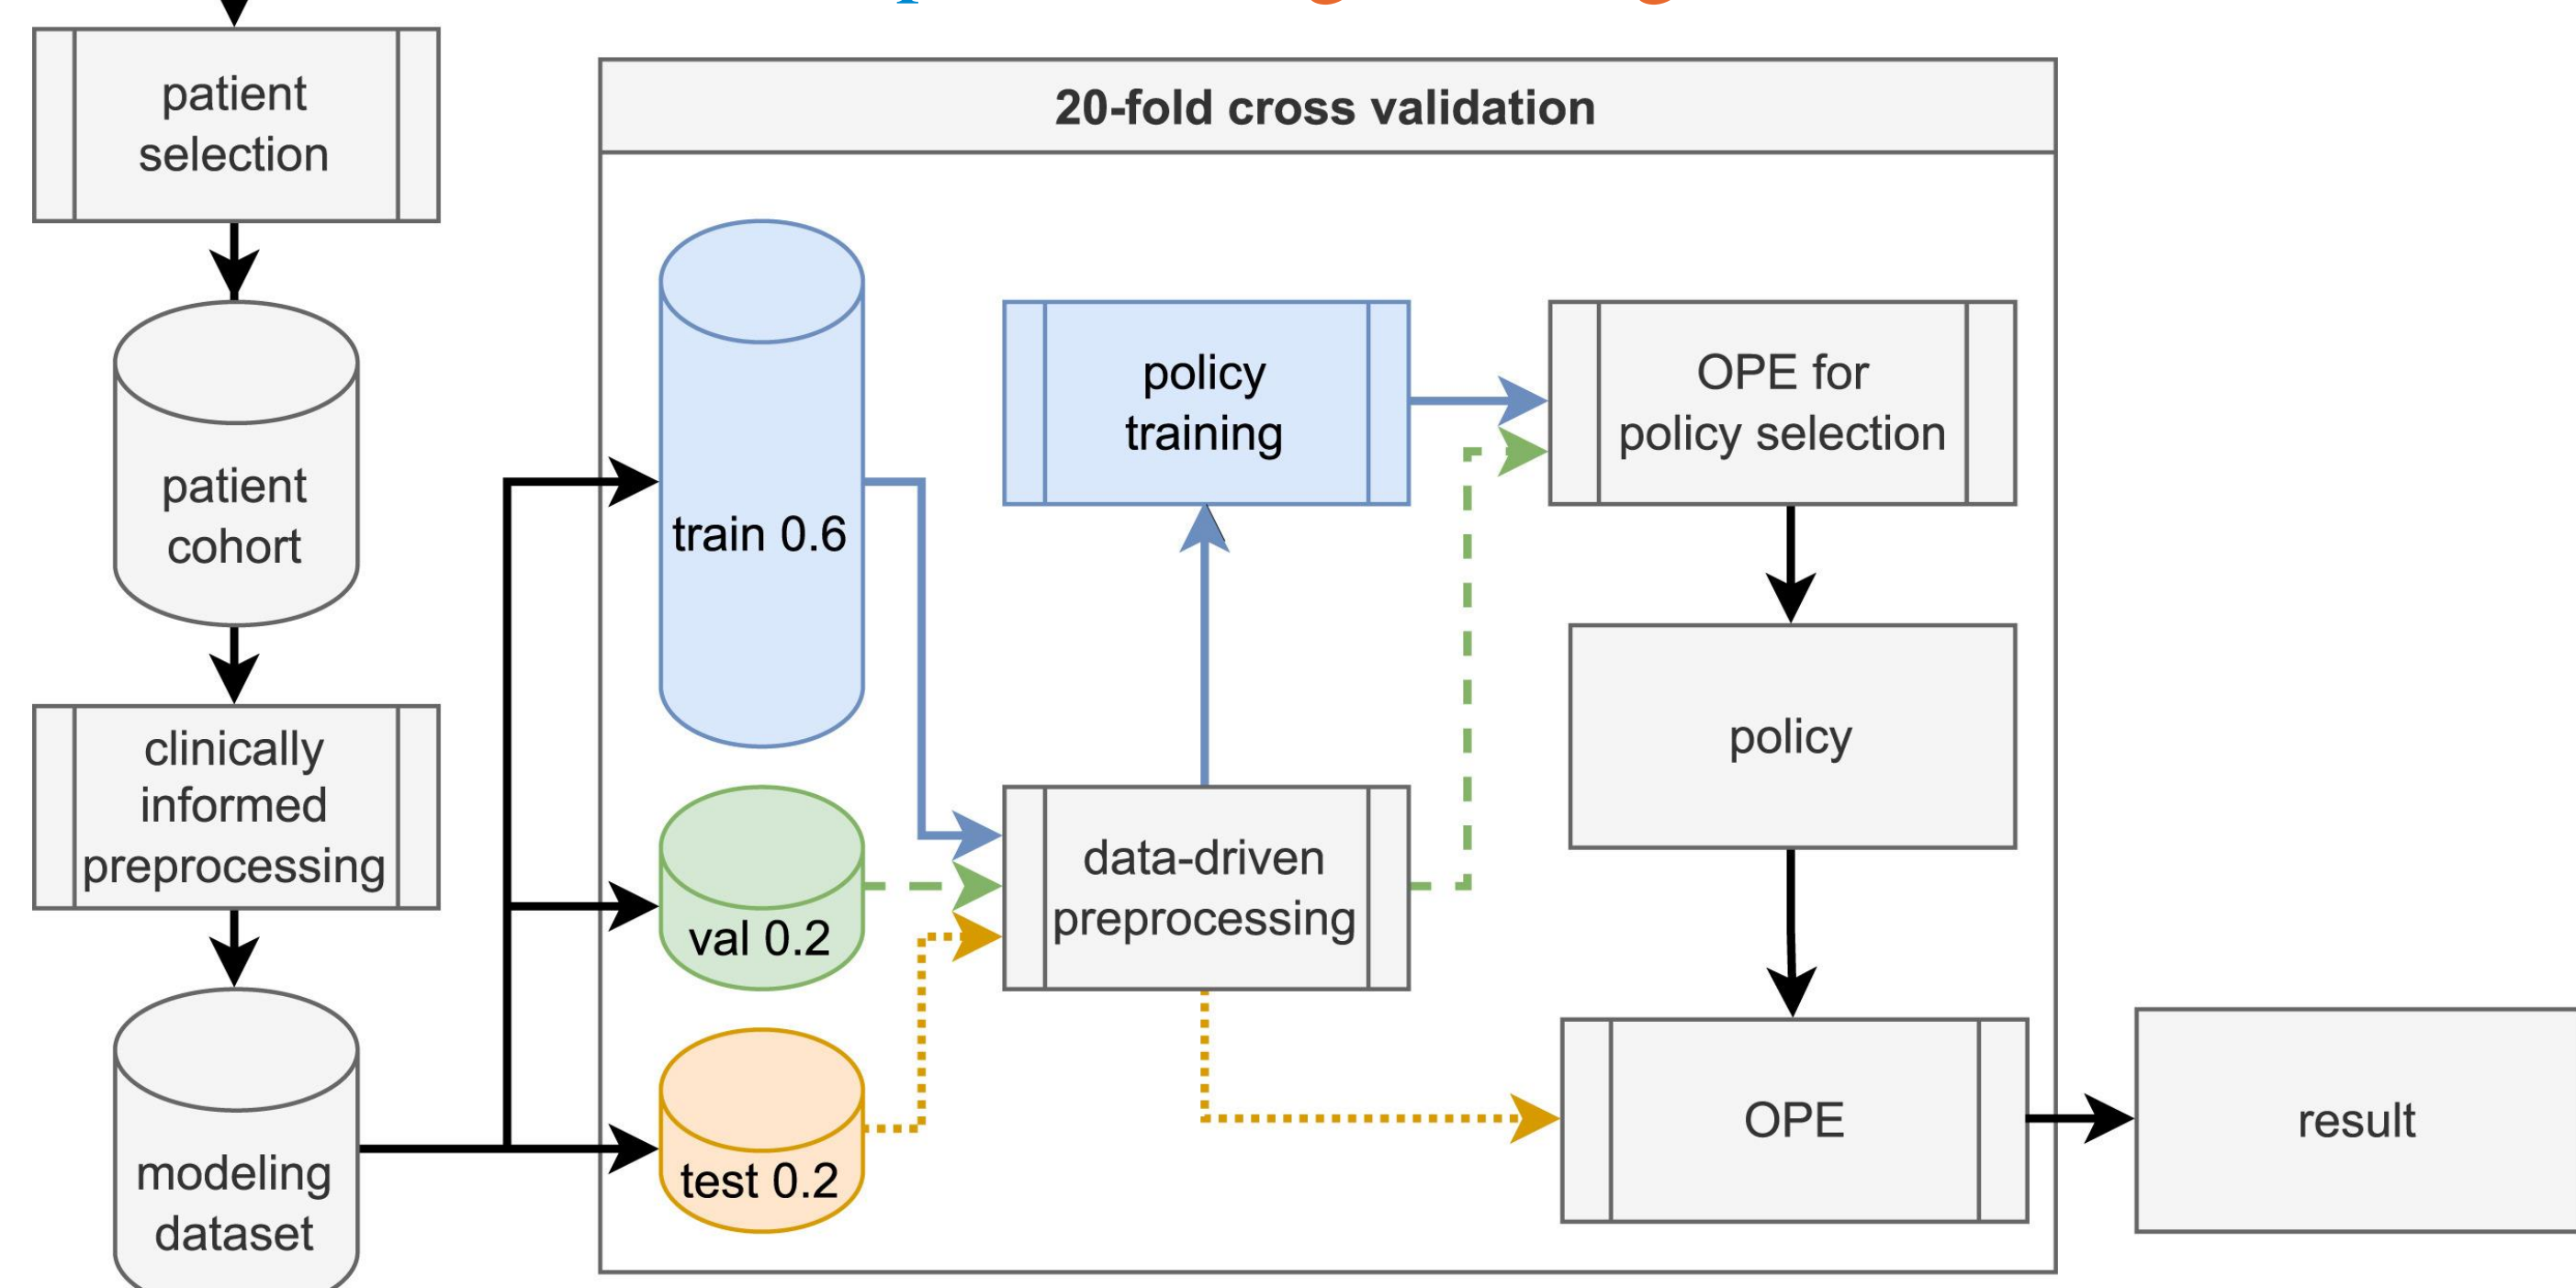

3) **State-space constraints** describe desirable properties in the patient condition. The learning agent is informed of state-space constraints with potential-based **reward shaping**.

5) The state representation and the agent actions are learned with offline RL

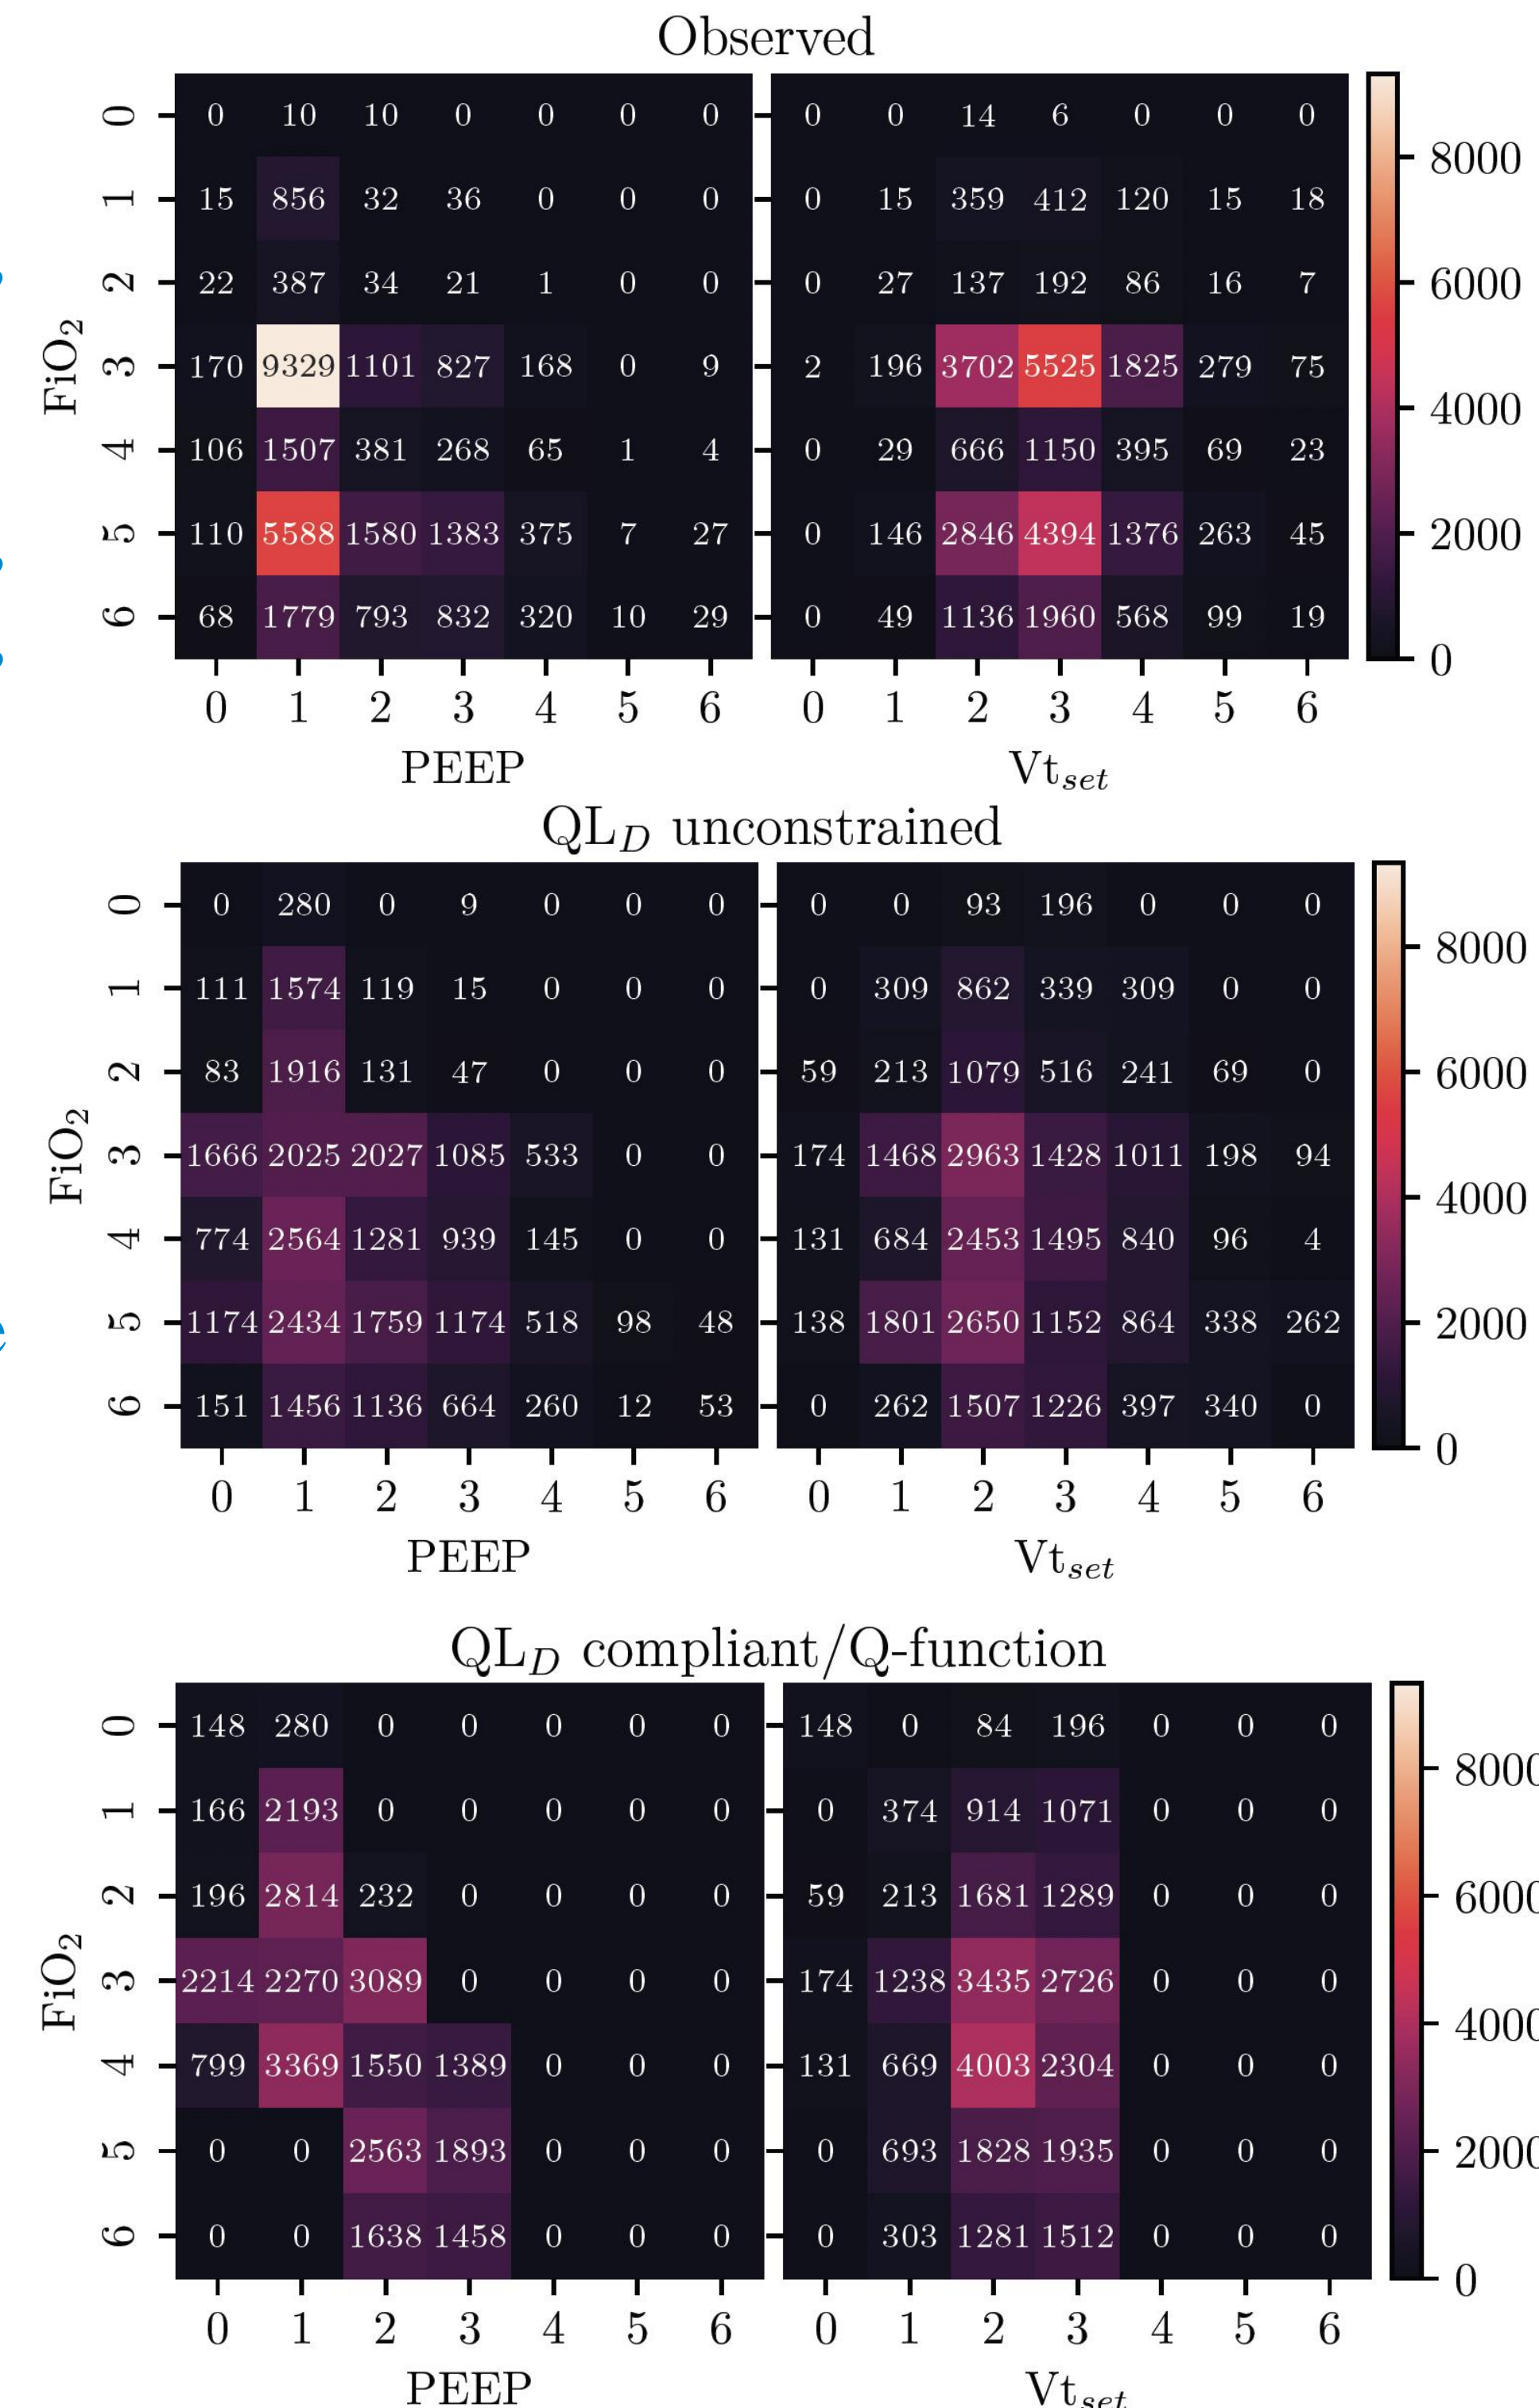

Data & Algorithms

Based on Peine et al., includes **stochastic & deterministic** versions of Q-learning.

We apply the action filter on the policy, **after learning** and in the Q-function update **during learning**.

Comparing Action Preferences

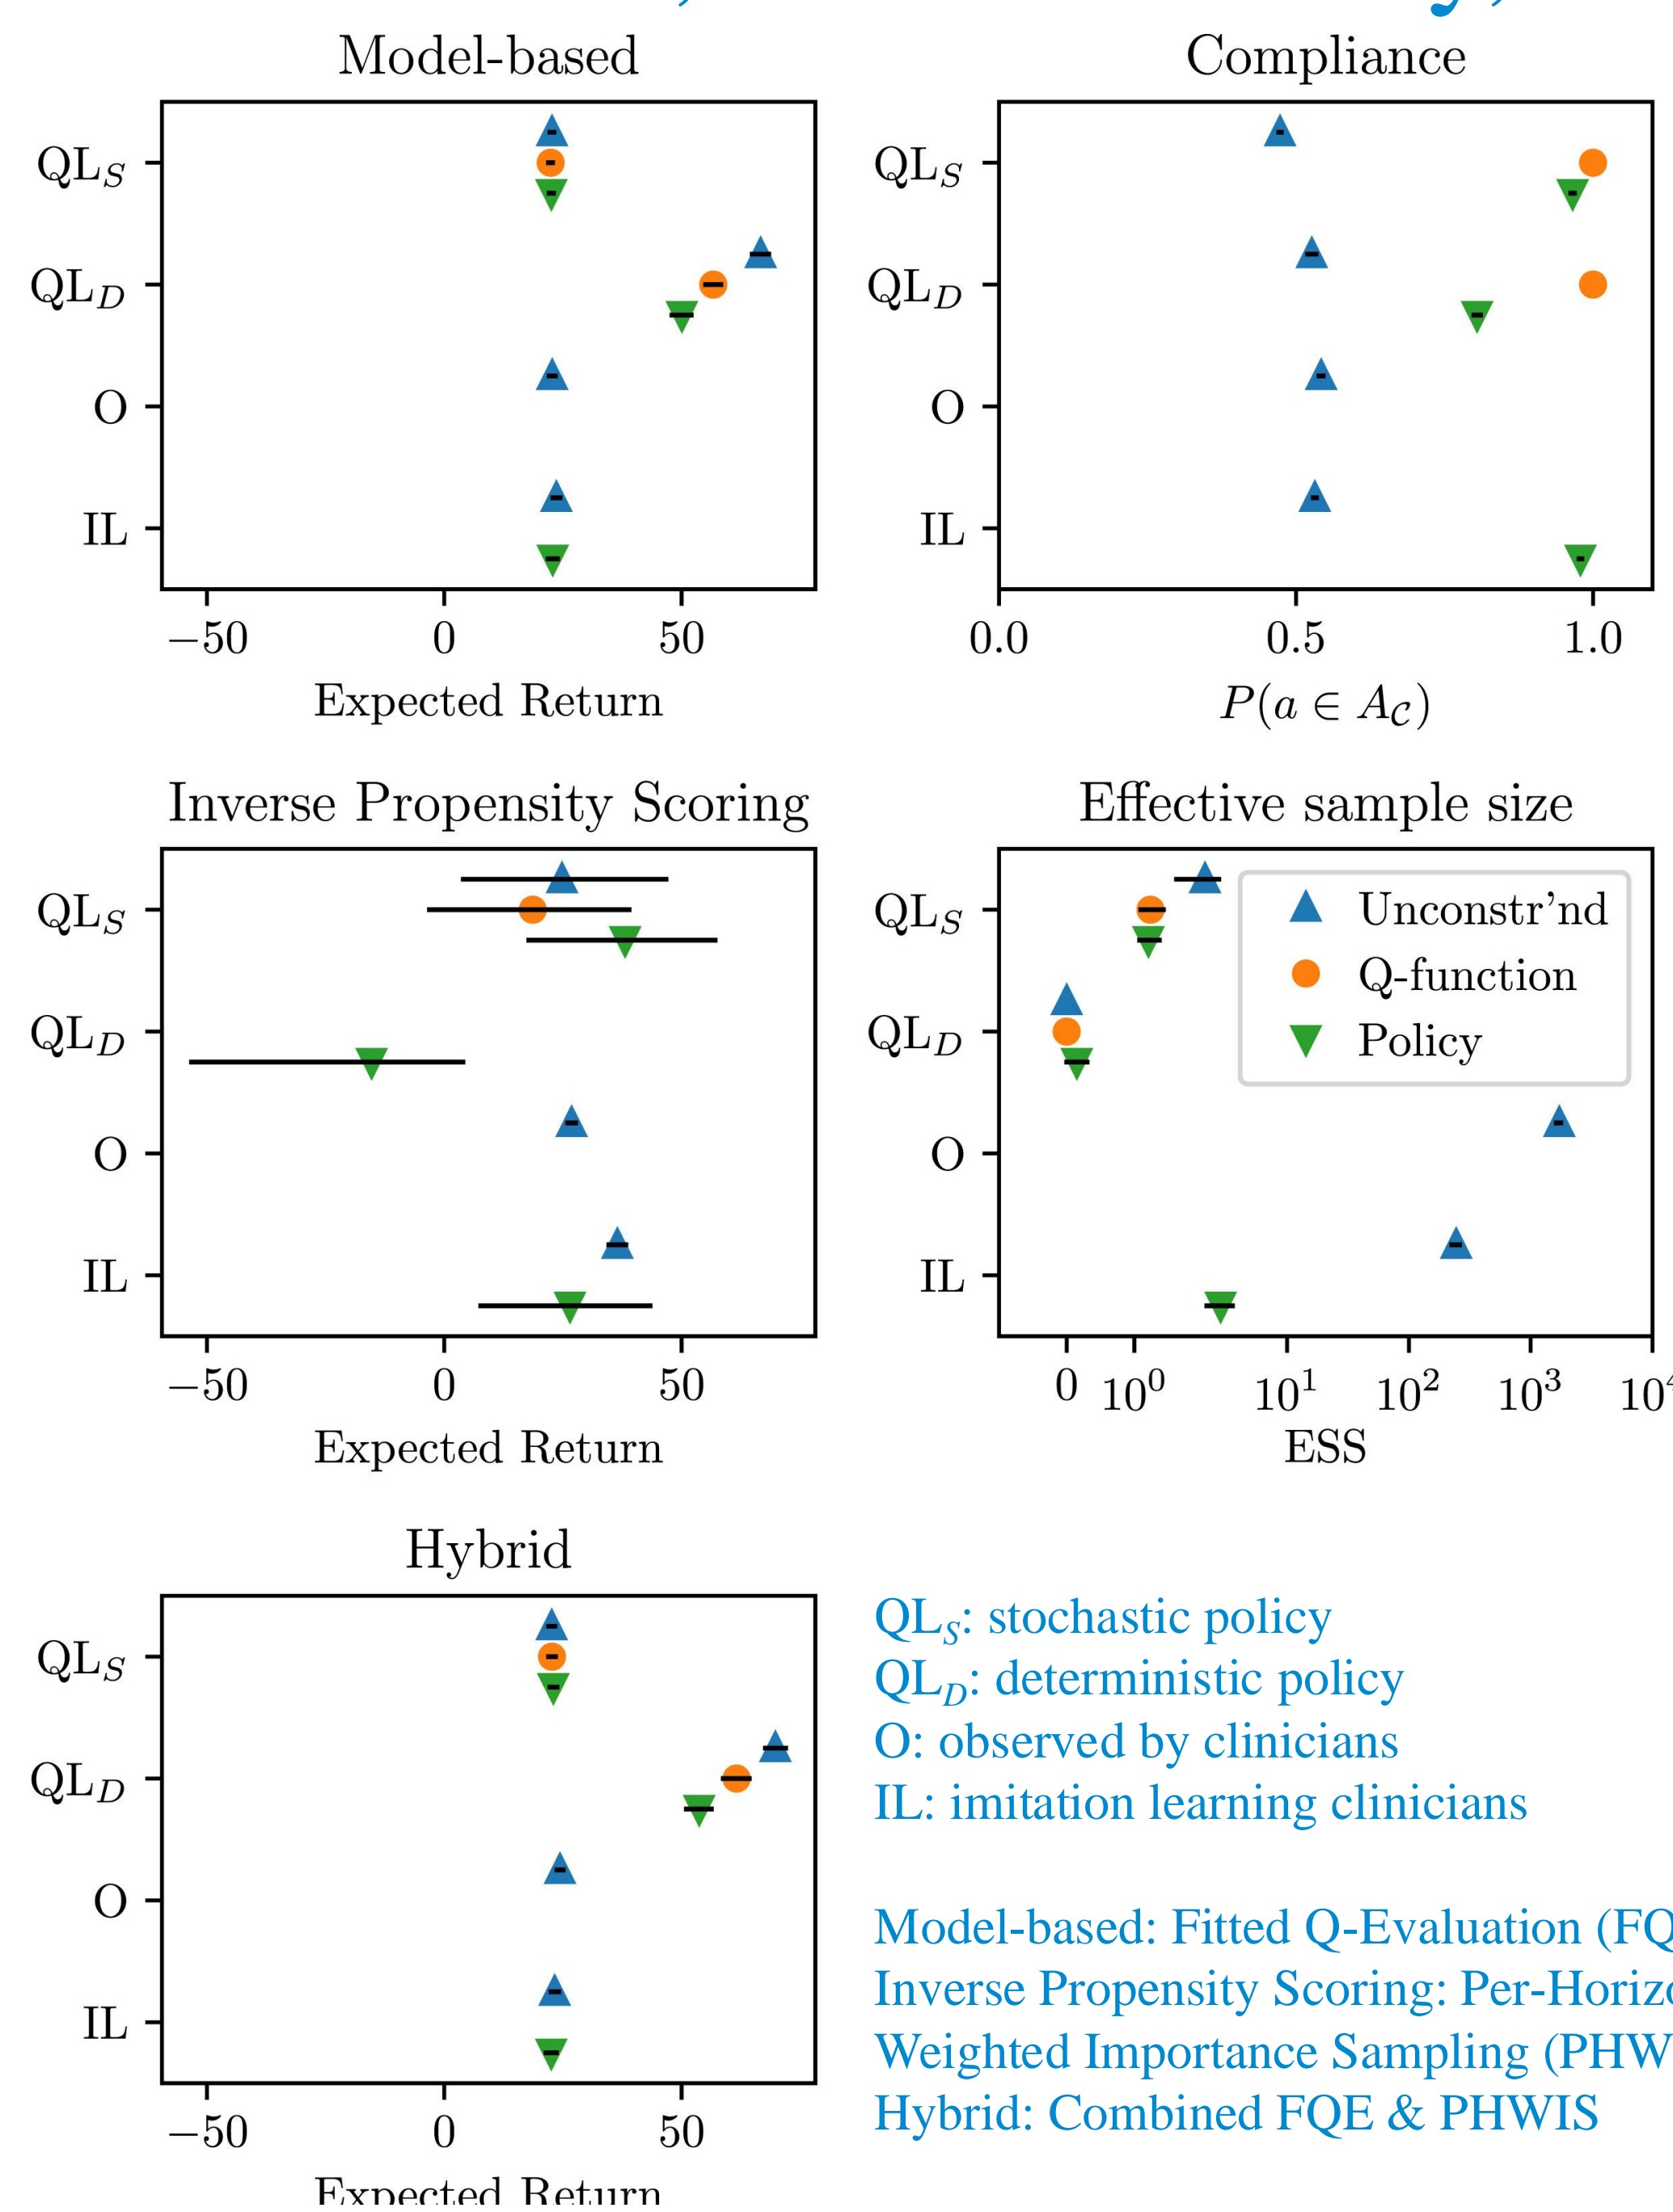

Learned & unconstrained, unsafe policies select **more varied actions** than those observed in clinicians

This may indicate **better adaptation** to patient conditions

Learned & constrained, safe policies **avoid extreme actions** that are not according to guideline

This may result in **more trust** by clinicians and hence **better adoption**

Results: Safe, Low Mortality, Small Samples

Learned policies are **more safe and better** (QL_D) than clinicians in a model-based evaluation

The **effective sample size** for deterministic safe policies (QL_D) may be **zero**

For stochastic policies (QL_S) and imitation learning (IL), the ESS looks much better, but is **still small**

This explain the **large 95% CIs** for IPS and Hybrid evaluations

Conclusions

Guideline-compliant RL to move RL to closer to clinical practice.

Varied policies that comply with the medical guideline while **outperforming** clinicians in terms of **expected mortality** in a model-based evaluation

No benefits in reward shaping: the training data were sufficiently rich for minimizing 90-day mortality.
